

# AVL: Rotaciones

Algoritmos y programación II (75.41 & 95.15)

Curso Mariano Méndez

Ideado por Adelson-Velskii y Landis

Tipo de ABB auto-balanceado

Su orden de complejidad se mantiene en O(log(n))

Factor de balanceo

Ideado por Adelson-Velskii y Landis

Tipo de ABB auto-balanceado

Su orden de complejidad se mantiene en O(log(n))

#### Factor de balanceo

Atributo que se le agrega a cada nodo

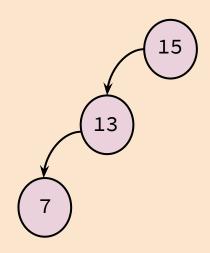

Representa la diferencia de alturas entre los árboles izquierdo y derecho

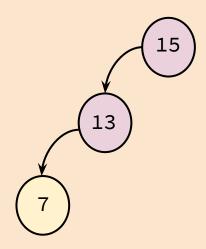

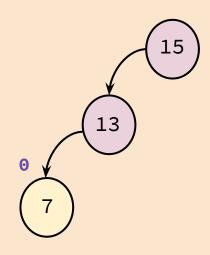

Valores permitidos: -1, 0, 1.

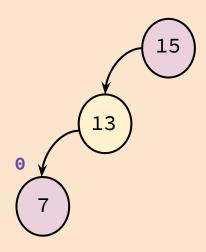

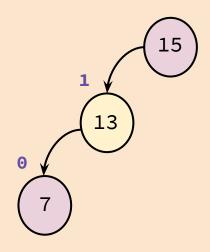

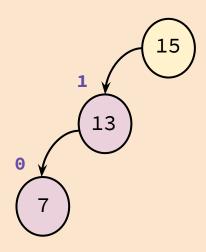

$$\Theta - \Theta = \Theta$$

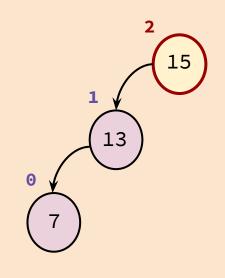

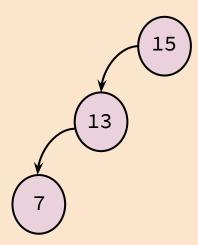

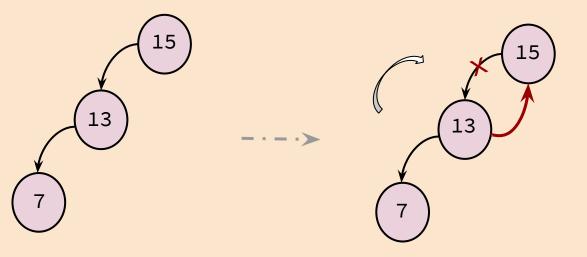

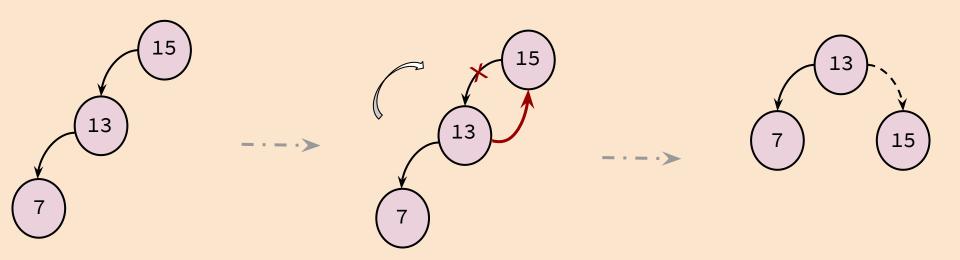

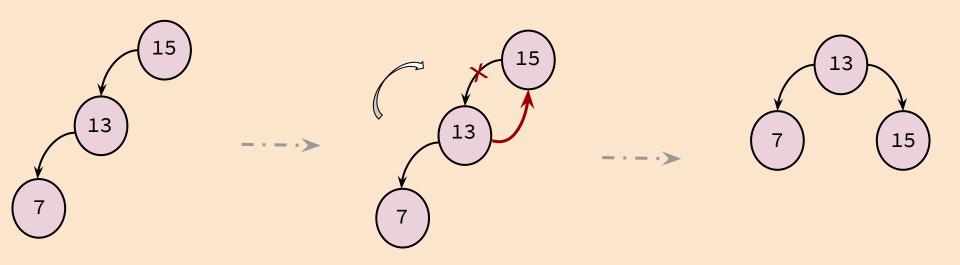

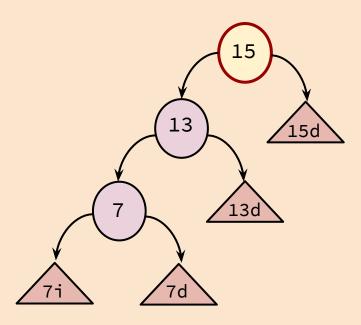

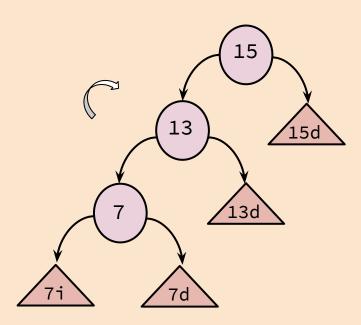

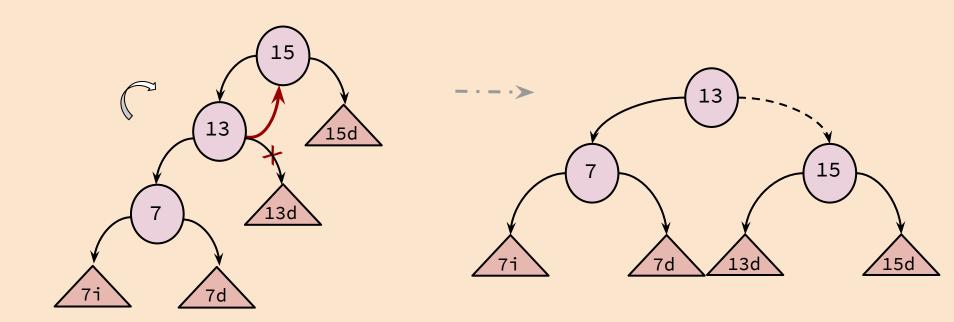

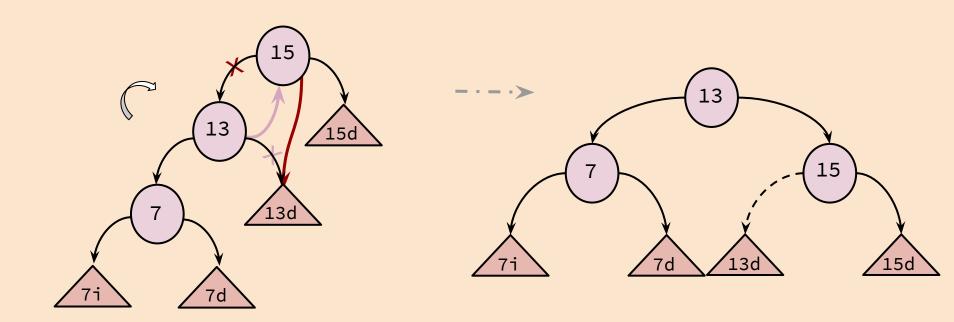

Y si los nodos tienen hijos??

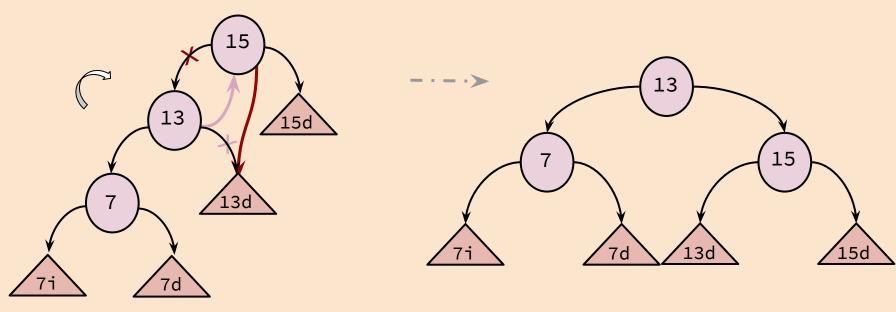

i = subárbol izquierdo
d = subárbol derecho 16

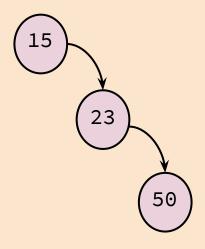

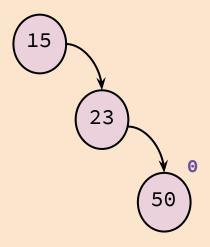

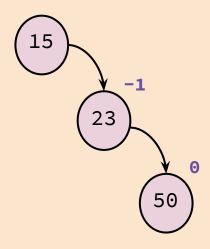

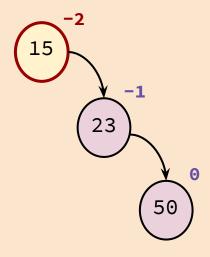

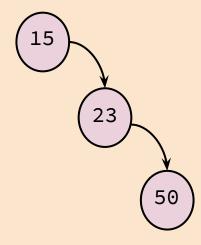

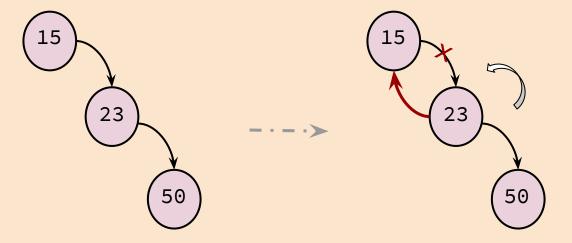

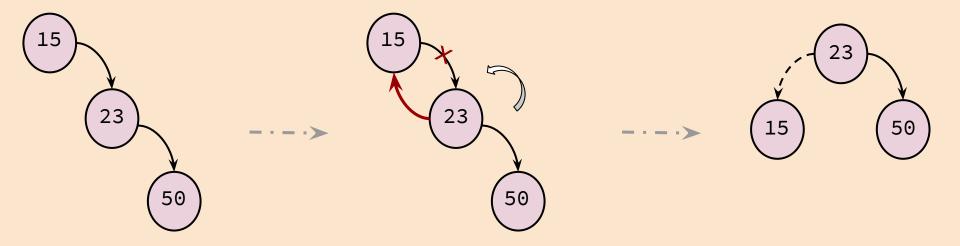

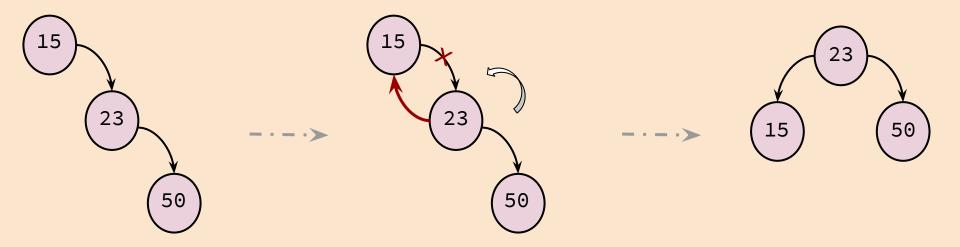

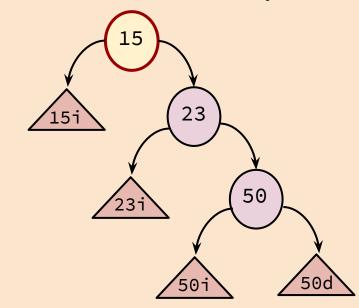

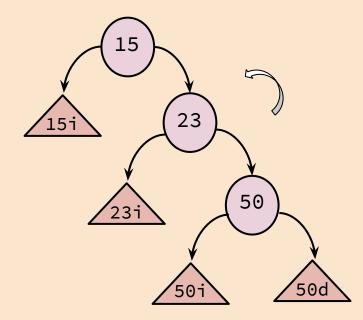

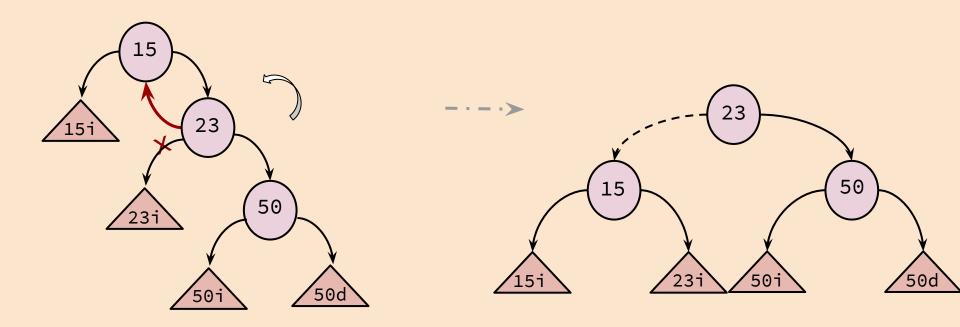

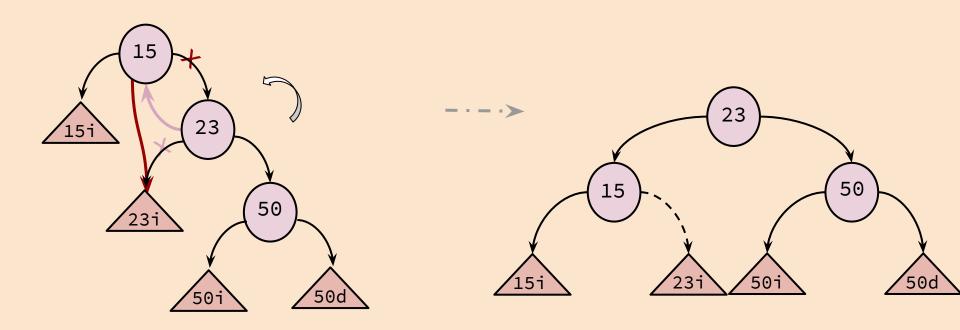

Y si los nodos tienen hijos??

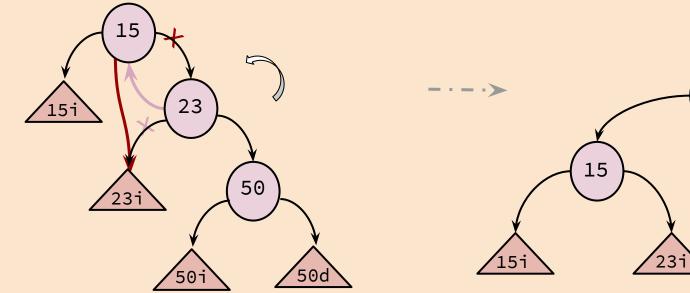

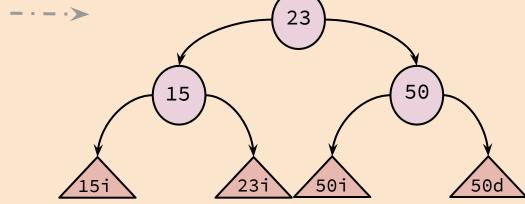

i = subárbol izquierdo
d = subárbol derecho 30

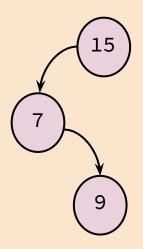

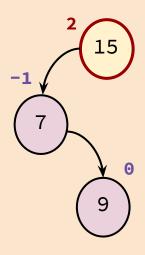

# Rotación a izquierda + rotación a derecha

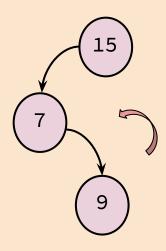

### Rotación a izquierda + rotación a derecha

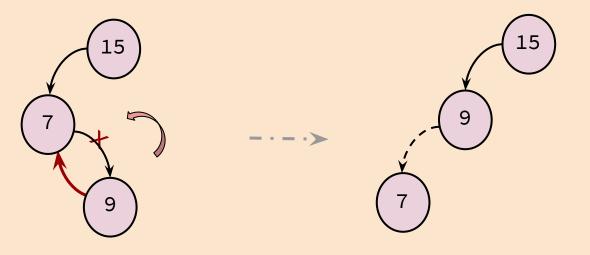

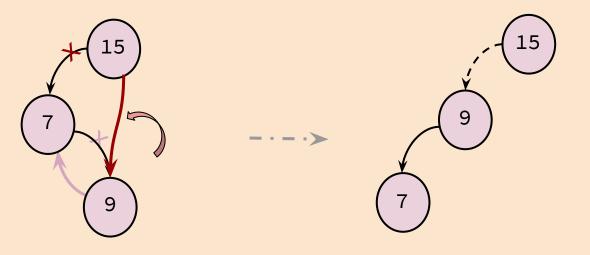

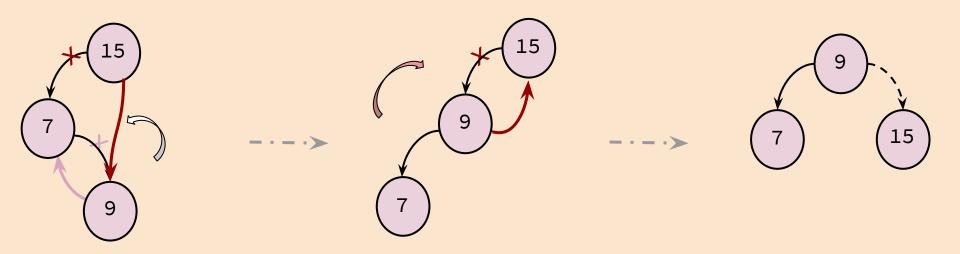

Factor de balanceo: altura izquierda - altura derecha

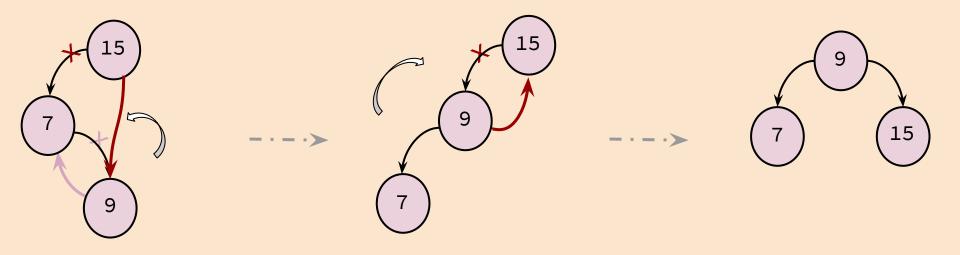

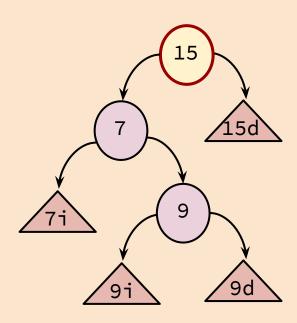

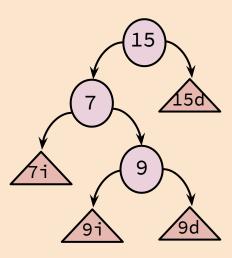

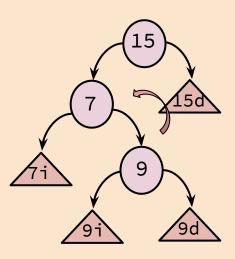

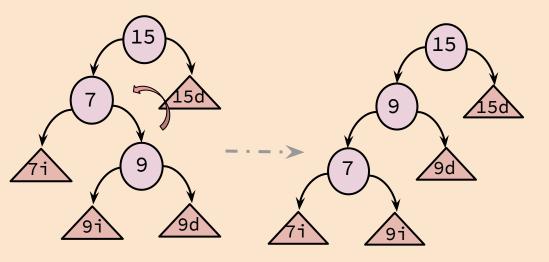

Con hijos:

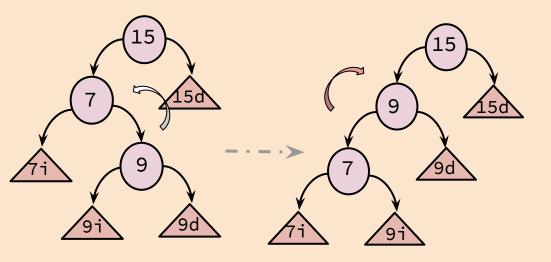

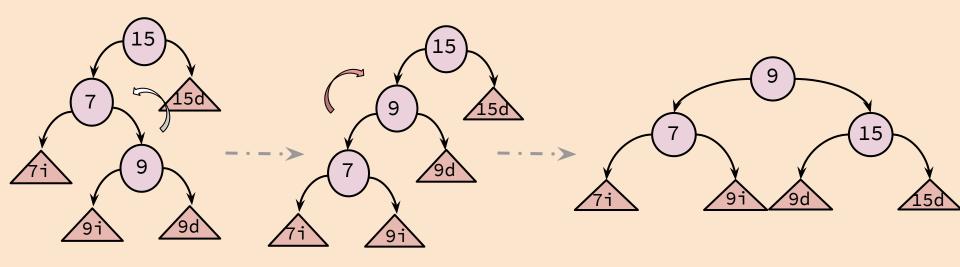

= subárbol izquierdo | = subárbol derecho 4

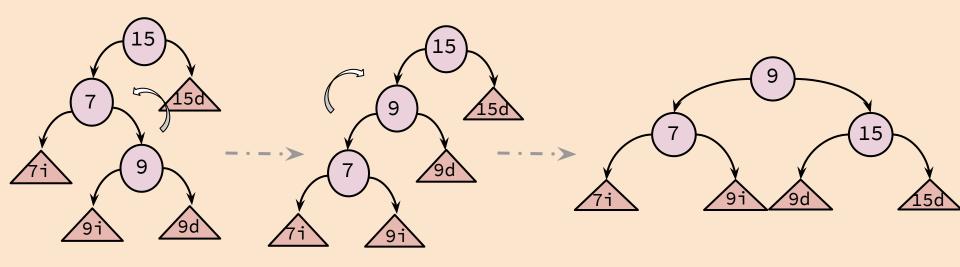

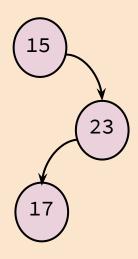

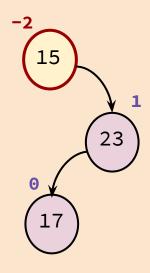

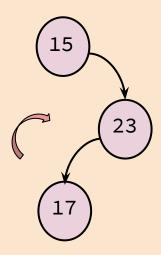

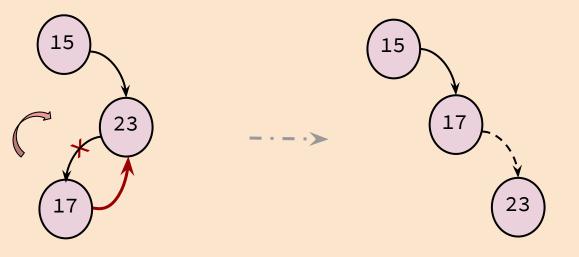

Factor de balanceo: altura izquierda - altura derecha

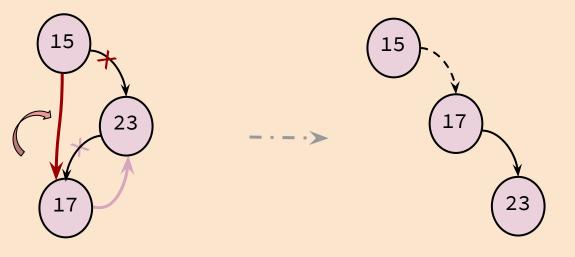

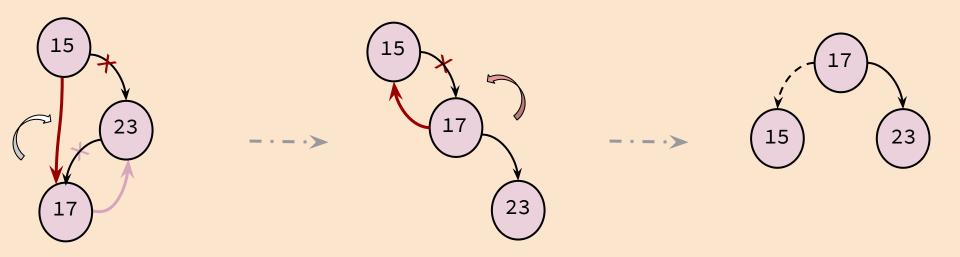

Factor de balanceo: altura izquierda - altura derecha

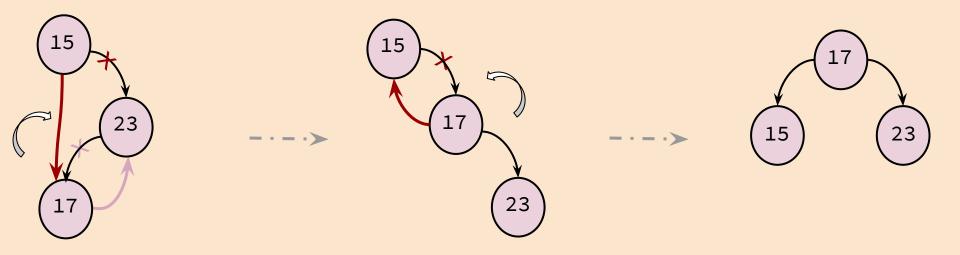

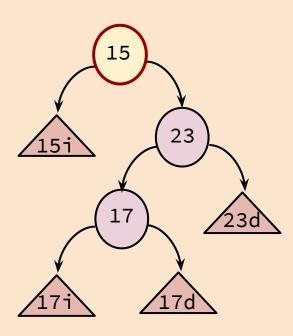

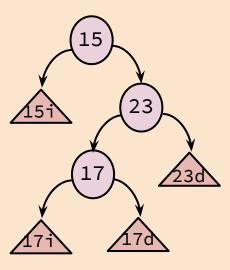

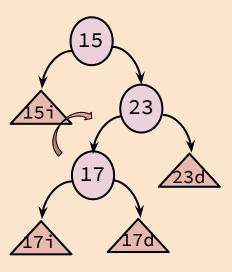

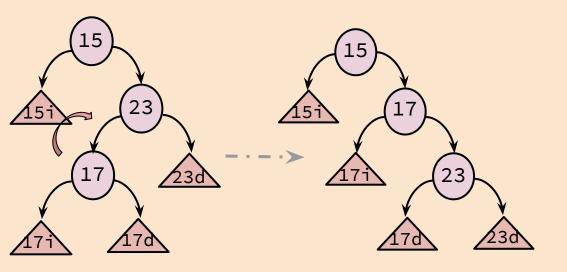

#### Con hijos:

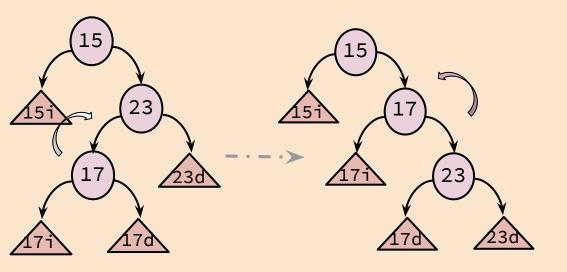

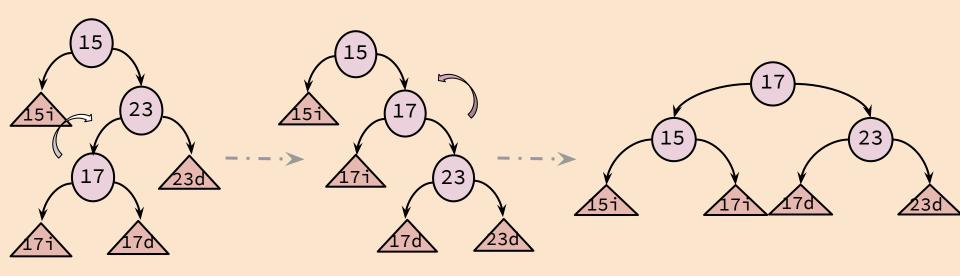

i = subárbol izquierdo d = subárbol derecho 58
